

## Issues:

- ① How to determine stability of CL<sup>sys</sup> from Bode Plot of OL sys
- ② How to relate Bode plot of Open Loop system  
To Frequency Response specs of CL (i.e to  $M_p$ ,  $\omega_p$ , BW) ?
- ③ How to design compensators to meet specs?

## Stability of CL system from Bode Plot of OL system

Consider

- All points on RL have the property

$$1 + KG = 0 \quad |KG(s)| = 1 \quad \angle G(s) = 180^\circ$$

- In particular, for  $s = j\omega^*$  (corresponds to neutral stability)

$$|KG(j\omega^*)| = 1 \quad \angle G(j\omega^*) = 180^\circ$$

- In agreement with RL system stable if

$$PM > 0$$

**PM:** Phase Margin

- the amount by which the phase of  $G(j\omega)$  exceeds  $-180^\circ$  when

$$|KG(j\omega)| = 1$$

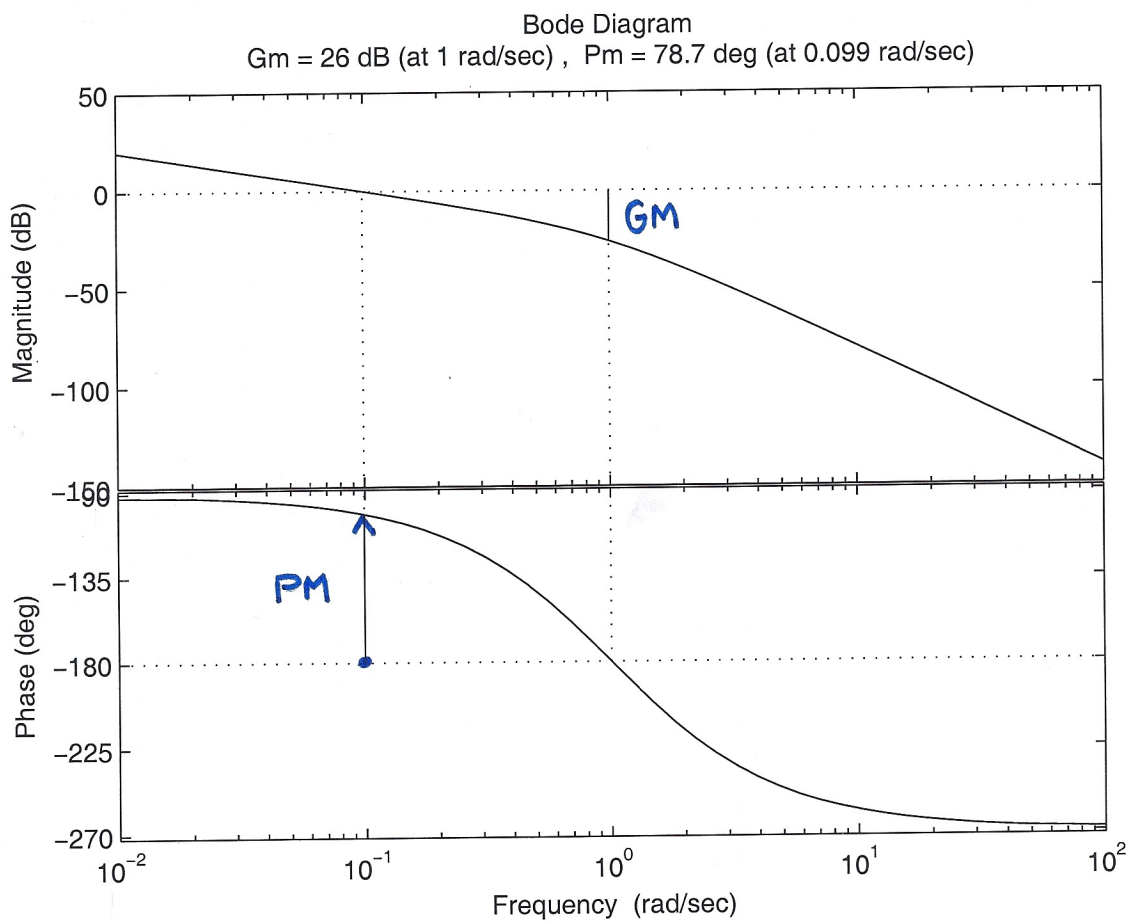

- GM:** Gain Margin  
: measure of how much the gain can be raised before instability results.

matlab Function: margin(num,den)

- $g = tf([0.1], [1 \ 2 \ 10])$  ← corresponds to  $k=0.1$
- $\text{margin}(g)$

Note

Matlab command

- `bode (g)`

gives Bode Plot with no PM & GM information
